

## GSA Annual Meeting in Denver, Colorado, USA - 2016

Paper No. 92-3

Presentation Time: 8:35 AM

### CARBON DIOXIDE AND HELIUM GASES IN NEW MEXICO: DISTRIBUTION AND RELATION TO OTHER GASES IN THE RESERVOIR (Invited Presentation)

**BROADHEAD, Ronald F.**, New Mexico Bureau of Geology and Mineral Resources, New Mexico Tech, 801 Leroy Place, Socorro, NM 87801, [ron@nmbg.nmt.edu](mailto:ron@nmbg.nmt.edu)

Carbon dioxide is a common component of natural gases. In most gases CO<sub>2</sub> is less than 1%, with either hydrocarbons or N<sub>2</sub> being the dominant components. In other less common gases, CO<sub>2</sub> is dominant and may constitute more than 99% of the gas. The major CO<sub>2</sub> reservoir in New Mexico is the Bravo Dome field in the northeast part of the state. This giant field with more than 10 TCF original reserves is formed by a combination structural-stratigraphic trap in the Yeso Fm. (Lower Permian) and has produced 3.5 TCF CO<sub>2</sub>. Gases that are mostly CO<sub>2</sub> are also present in the Las Vegas and Raton Basins of north-central New Mexico and under Chupadera Mesa and in the Estancia Basin of central New Mexico and have also been encountered by exploratory wells drilled in west-central New Mexico. The main source of CO<sub>2</sub> appears to have been degassing of Tertiary-age magmas.

Commercial production of helium in New Mexico has been from 8 small oil and gas fields on the Four Corners Platform of northwest New Mexico. Almost 1 BCF He have been produced from reservoirs of Permian, Pennsylvanian, Mississippian and Devonian age. In southeast New Mexico gases with enhanced He content have been produced from Lower Permian Abo red beds with He content increasing in proximity to northeast trending strike-slip faults. Gases with enhanced He content have been encountered in Lower Permian strata under Chupadera Mesa in central New Mexico and in Pennsylvanian strata in the Tucumcari Basin. Although most He in crustal reservoirs has probably been generated by radioactive decay of uranium in granitic rocks, isotopic analysis of Chupadera Mesa He indicates that a portion of the He was derived from juvenile sources in the mantle.

There is an inverse correlation between He content of gases and CO<sub>2</sub> content and hydrocarbon gas content. Most gases with CO<sub>2</sub> more than 5% have He less than 1%. All gases with CO<sub>2</sub> more than 20% have He less than 1%. He content also decreases with increasing BTU value of the gas, a proxy for hydrocarbon content. All gases with heating values more than 1000 BTU/ft<sup>3</sup> have He substantially less than 1%. He increases with N<sub>2</sub> content, an indication of incomplete charge of reservoirs with either hydrocarbons or with CO<sub>2</sub>. CO<sub>2</sub> and hydrocarbons appear to dilute the He that has migrated into the reservoirs from either granitic basement or via deep-seated faults that penetrate to the mantle.
